Introduction

Monitoring of the ecological state of Black Sea coastal ecosystems on the basis of structural-functional organization of macrophytobenthos communities has a number of advantages:

- macrophytes are primary producers, being the first autotrophic link in the ecological transformation of matter, and as a result of which are the first to react to changes in the ecological state of the coastal ecosystem;
- macrophytes are attached organisms, inhabiting coastal biotopes which to greater degree undergo anthropogenic impact and are the most valuable for monitoring;
- macrophytes are macro in dimensions and are widely distributed in the coastal ecosystems making them convenient for monitoring as technically their study is simplified;
- macrophytes have long life cycle to present an integrated response on the environmental status;
- macrophytes are presented by large dominant species, which form an indicator community - *Cystoseira*, *Zostera*, *Phyllophora*;
- macrophytes communities have a sensitive structural-functional organization which well reflects the variability of the environmental conditions.

The biggest problems to use of macrophytes in monitoring are:

- underwater visual observation with the usage of a higher technology equipment (diver outfit, underwater camera, ROV and others);
- expensive methods of sampling;
- destroy the nature structure of community under the breaking waves on the upper horizons (loss of real phytobiomass).

The parameters of structural-functional organization of macrophytobenthic communities include: floristic composition, abundance, biomass, morphological parameters and difference indexes which respond to change in quality of a substrate, illumination, hydrodynamics, salinity, concentration levels of nutrients and toxicants. These parameters may be used as monitoring parameters illustrating the integral reaction on abiotic condition of benthic plant communities to changes occurring in coastal, shallow water ecosystems. Especially useful for monitoring the trophosaprobiontic state of coastal waters are indices of a surface of macrophyte algae (Minicheva, 1987, 2003).

Use of macrophytes for the estimation of Ecological Status Class of coastal ecosystem in accordance with the requirements of EU Water Framework Directive (WFD) and EU Marine Strategy Framework Directive (MSFD) allowed also to offer the row of new indicators of the macrophytes based on morphofunctional parameters: Three Dominants Ecological Activity (S/W3Dp); Average Species Ecological Activity (S/Wx); Phytocenosis Ecological Activity (S/Wph); Phytocenosis Surface Index (Siph) (Minicheva, 2013).

The main aims of monitoring of macrophytobenthos communities are to:

- control changes in spatial distribution and abundance of macrophytes, including evaluation of the percentage of macrophyte coverage of substrate;
- control changes in floristic composition in communities, the laminar structure (epiphyte - basiphyte);
- control changes in the structure of organization of the community including abundance and biomass;
- control changes of the morpho-functional organization including a specific surface of separate species and the total surface of community;
- control of indicators (see Appendix 3) reflecting a change of Ecological Status Class of coastal ecosystem in accordance with the requirements of WFD and MSFD.

The results of control are the main for analysis of short and long term reactions of macrophytobenthos to change of environmental conditions in the coastal ecosystem caused by man-main impact:

- replacement of natural substratum (hydrotechnical construction);
- disturbance of benthic biotope (trawling, dredging, dumping);
- lowering of transparency, increasing of levels of nutrients and toxicants.

1 Sampling

1.1 Sampling equipment and technical means

Equipment for qualitative sampling macrophytes

For scrubbing (cutting the rhizoidal part) of the thallus on hard surface substrates *a scraper* is necessary. It has a handle of light floatable material and a surface made up of stainless steel, a sharp edge with 5-7 cm wide base. Scalpels or other cutting instruments may be used.

For scraping the surface macrophytes from vertical walls of hydrotechnical constructions part of which are above water, *a scraper with the long handle* is used which has the form of a frame one edge of which is sharp. The scraper is equipped with a mesh bag for catching algae thalli. A *dredge* of usual construction is used from board ship sampling benthic hydrobionts. Visual assessment of macrophytobenthos distributions is performed. At great transparency a box with a glass bottom may be used.

Equipment for quantitative macrophyte sampling.

Frames for quantitative calculations are used for sampling macrophytes on a certain surface area of a seabed. Contour frames may be used for those areas protected from waves with soft seabed where meadows of marine grasses develop. These frames are 100x100 cm of different material which as a rule are not bound by mesh nets, and are lowered on macrophyte meadows limiting the dimensions of the community to one square meter, and vegetation is carefully extracted. This method can be used at small depths and in conditions of calm weather to avoid loss of samples. It is more convenient and reliable to use *periphyton frames* on firm and soft natural substrates, as well as on artificial surfaces of hydroconstructions. The periphyton frame is a contour made of stainless steel, one side of which has a gently sloping surface for better slipping of thallus. It has a sleeve from a mesh net used for collecting all of the thalli. The scraper is put into the sleeve with one hand, while the explorer fixes the frame on the substrate algae surface with the other. The algae are thoroughly scraped off under water, placed in one of the corners of the sleeve. The thallus is then removed from the frame sleeve above water. Depending on the type of substrate periphyton frames of 10x10 cm; 20x20 cm; 20x40 cm may be used (Fig.1.)

Fig.1. Scraper and periphyton frames for the quantitative samples of macrophytobenthos

When working on board ship, for quantitative calculation of macrophytes the Petersen grab sampler or «Ocean» sampler 0,1 or 0,25 m² opening is used (Guide...,1980).

Only in the supra- and pseudolittoral the sampling of macrophytes is possible without special underwater equipment. The explorer may use *rubber boots* or *overalls* and a small *floating platform* (penoplastic, pneumatic mattress), tied to the belt and pulled with the samples and other accessories. At a depth of 60-70 cm (the length of an outstretched hand) it is necessary to use underwater technical means and SCUBA. For visual assessment an underwater mask with a wide vision is used. An underwater camera, may be used to take pictures of typical sites of phytocenoses. At a distance from sampling sites from the coast, ships and other means may be used for diving. Otherwise the abovementioned dredge and grabs are convenient.

1.2 Strategy of sampling

In a coastal area

On rocky and gently sloping natural shores formed by hard ores or sediments, in layers from supra- to lower sublittoral, it is more convenient to apply the method of *linear transects* or *cuts* (Gromov, 1973). Cuts are laid perpendicular to relief of shores towards the sea. Using the natural borders of growth of characteristic associations of macrophytes, the layers in the cut are defined for sampling. For example for the cape part of the open coast the following layers can be selected: [+1 m – 0 m]; [0 m – 0.5 m]; [0.5 m – 1.5 m]; [1.5 m – 3.0 m]; [3.0 m – 5.0 m]; [5.0 m – 10.0 m]. In each layer at 10-15 meters aside from the conditional line of the cut visual evaluation of phytocoenoses is done. The percent of projected coverage of bottom of macrophytes is determined, the tier, abundance according to the Drude scale. Information is recorded by a diver under water on special plastic plates. Depending on the structure of phytocoenoses and heterogeneity of the spatial distribution of macrophytes on each of the layers 3 -10 frames of quantitative account are made.

In the coastal areas with a considerably changed coastline (technogenic, recreational areas), with even surfaced hydrotechnical constructions, it is possible to use an exposition-belt method for macrophytobenthos sampling. For this it is necessary to determine the artificial surfaces the exposition of which reflects all heterogeneity of environmental conditions of the area. For example, walls of traverses, breakwaters, booms or piers located at different angles or in the conditions of different wave action are used as, model surfaces for macrophyte sampling. For artificial surfaces located, as a rule, vertically, or having a small slope angle, a distinct narrow belt of mono- or phytocoenoses of macrophytes is selected. On vertical surfaces the width of belts covered by typical associations is from 20-50 cm to a few meters. In accordance to this distribution of belts, sampling layers are determined, similar to the method of linear cuts on a natural coast.

In open water

During work at a considerable distance from the coast on floatins without a diver, it is not possible to make visual evaluations of macrophyte growths. In this case it is impossible to estimate the percent of projected coverage of bottom with macrophytes, and impossible to select the areas of the most dense growth of macrophytes. Correspondingly, it is not necessary to sample 100% coverage with macrophyte biomass vegetation on the meadow. (Biomass vegetation "on the meadow" for 100% coverage). In this case it is necessary to take into account when planning the network of sampling stations, that the material obtained, will be a random sample, for all of the explored area, which, as a rule, to 100% is not covered by the macrophyte vegetation. In the case when research is conducted at an identical depth (for example, exploring of the «fields» or «meadows» of macrophytes) the net station network has the appearance of squares of evenly covering the explored area. The distance between the stations is determined on the basis of spatial heterogeneity of growth. At one station not less than three fold quantitative samples are made with

grabs. On transect between the stations for high-quality estimation, it is possible to use bottom dredging.

1.3 Determination of projective cover percentage using underwater video equipment

The method is based on underwater video recording of macrophyte communities (filming of registration video tracks) and conversion of the footage received into graphic form with further processing and counting using graphic editor.

The sequence of operations aimed at receiving of percentage of bottom projective cover with macrophytes could be divided into the following stages:

Filming of registration video tracks

Filming is performed under high water transparency using video camera in underwater housing. Laser pointers are attached on both sides of the camera (the usual distance between pointers is 50 cm) (Fig.2). For filming the camera is located perpendicularly to substrate and moved smoothly keeping the distance from the bottom or other surfaces covered with macrophytes.

Fig.2. Underwater camera with the laser pointers

Video sequence division into separate shots and selection of the images required to stitch panorama

The footage (or its fragments) are imported to video editor (the most common are Adobe, Canopus, Sony Vegas) having the function of video fragment division into a sequence of separate shots (Fig. 3). The shots are exported into a separate folder.

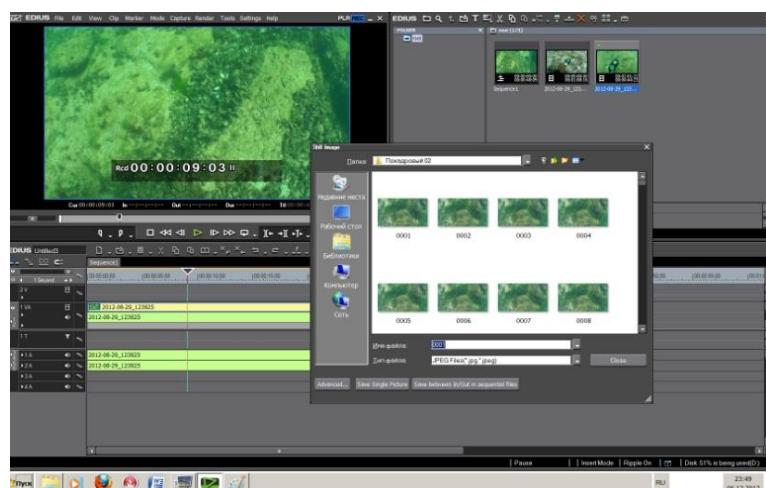

Fig. 3. Video track division into sequential shots

To form up the panorama selection of every 15th -20th shot is enough. At higher speed of camera it might be every 10th -12th shot, at lower speed - every 25th -30th one. The chosen shots are selected and copied to the separate folder .

Panorama stitching

The chosen shots are imported to panorama stitching software (PTGui Pro 9.) Than the low-informative edges of shots are cut off (10-15% on each side) to bring down distortion of the panorama (Fig. 4.).

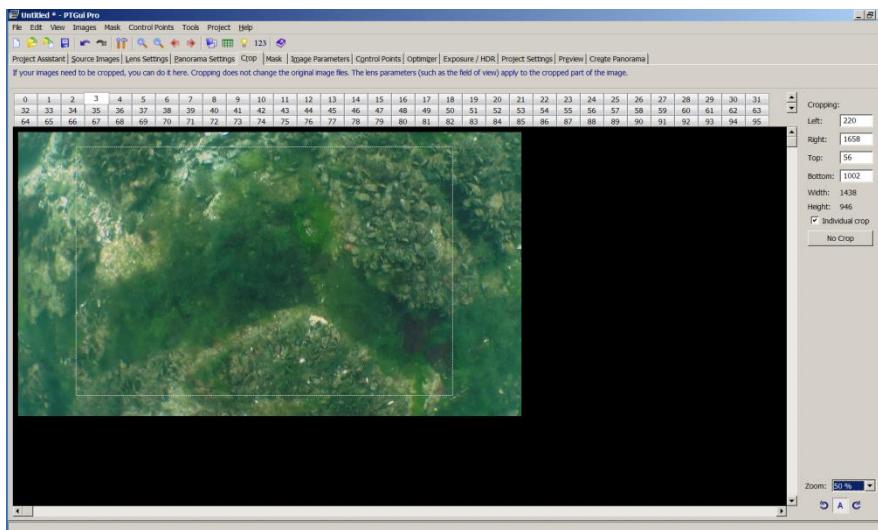

Fig. 4. Determination of low-informative edges of shots

At the next stage common (control) points should be found on the neighboring shots. Manual establishing of control points on the neighboring shots is possible. It is preferable to have minimum 3-4 common points between the neighboring images (Fig. 5.).

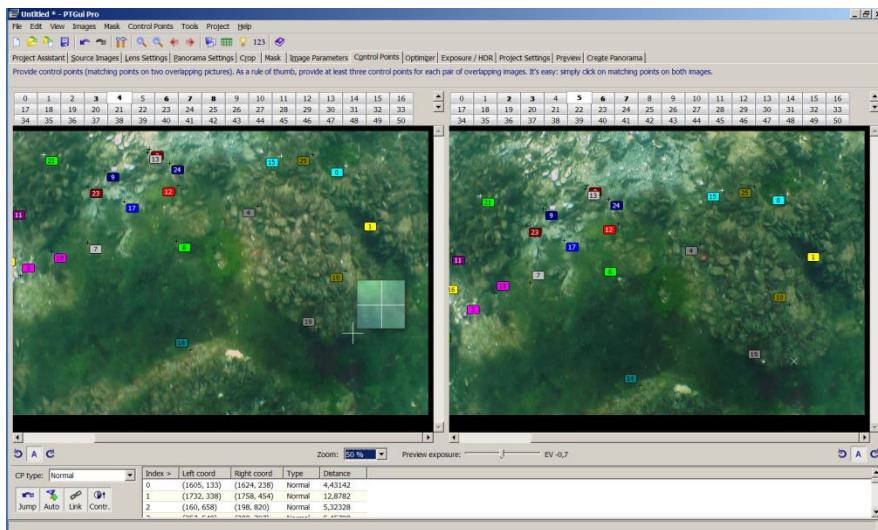

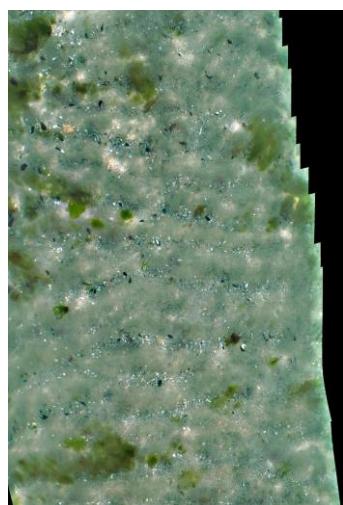

Fig. 5. Choice and positioning of control points

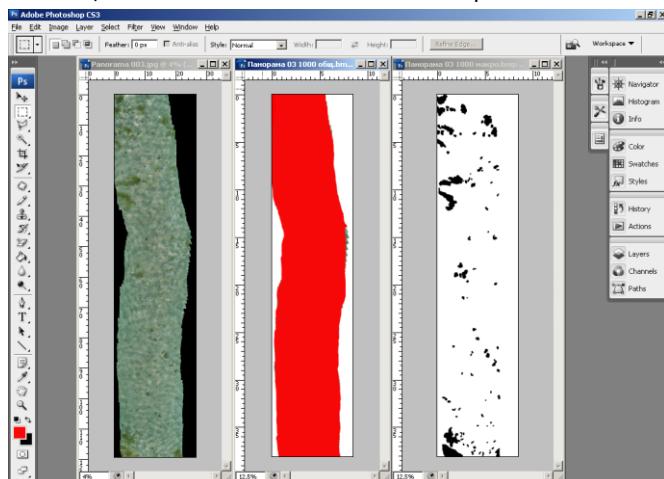

Further on image enhancement function should be switched on in the program. After that panorama stitching function could be started. An example of ready panorama is presented on Fig. 6.

Fig. 6. Example of panorama of sandy bottom with macrophytes

Selection of fragments of graphic image

The received panorama is imported to graphic editor (Adobe Photoshop). The next task is color highlighting of studied plot area and area covered with macrophytes. To do this the new layer is created, on which the area of entire panorama is shown in chosen color, for example red. Then

another layer is created, where the plots covered with macrophytes are shown in another contrast color, for example black (Fig. 7). It would be beneficial to save those layers as JPEG or BMP images with reduced resolution.

color

Fig. 7. Highlighting of panorama general area and macrophytes with

Projective cover area calculation

To calculate the percentage of bottom cover with macrophytes the panorama is imported into the program for curvilinear figures square calculation IpSquare 1,8. Select part of the panorama of chosen color with a click of cursor, than use the button «Calculate area» on the screen and the value of the area will be shown in a special box. Area of the studied plot is taken as 100%. Area of macrophytes cover is taken for x. Percentage of bottom or another studied surface cover with macrophytes is calculated according to respective proportion.

1.4 Fixing

Each macrophyte sample should be placed in a plastic or gauze bag and supplied with a detailed label with information about the sampling place and conditions. Fixing of samples may be permanent or temporary. It is assumed that temporary fixings of macrophyte samples is up to the time of their delivery to the laboratory (not more than 12 hours). The basic condition of temporary fixation is very thorough deleting of water from thallus, with gauze napkins or filter paper and temporary storage in portable ice chests. The permanent fixing of macrophyte samples is carried out with 4% solution of formalin or > 40° alcohol. Macrophytes may be frozen for long storage.

2 Treatment of samples

2.1 Washing

The first obligatory procedure before the beginning of treatment of samples in laboratory conditions is washing of macrophyte samples. The sample is placed in separate vessels of 3 - 10 liters volume and filled with running water. It is agitated by circular motions of thalli, forcing them to float while the rest of hard particles precipitate. The washed thalli are poured into a benthos sieve, with small mesh. The sediment is removed and the procedure is repeated 3 - 5 times to reach the state of a clean bottom.

2.2 Species identification

The washed sample is placed in a spacious cuvette with clean water. The algal mass is straightened with pincers and similar species thalli are identified. Special attention is paid to the presence of small epiphytes on thalli of large perennial species. From the thalli of each species a preparation is made on a glass slide for microscopy. Transverse or longitudinal cuts are made if necessary. For this purpose the thallus is clamped between two blocks of parenchyma of two-year old shoots of the elder (*Sambucus*) bush, and a cut is made with a sharp razor. Species determination of algal macrophytes of the Black Sea is carried out according to keys (Zinova, 1967; Vinogradova, 1974, at all see Annex 1, 2).

2.3 Determination of mass and quantity

Before determining the mass of the macrophytobenthos sample, it is obligatory to separate all of the species in the sample obtained with a periphyton frame or grab. The analysis of macrophyte samples is conducted in flat cuvettes with a wide bottom, in water, using pincers. If it is an epiphyte attachment the thallus is separated with a scalpel. The sorted out species are placed in Petri dishes or in other suitable laboratory glassware. Each sample is weighed separately. Depending on the dimensions of the species, it is possible to use different types of torsion or electronic balances giving a 0,01 g accuracy. As weighing of macrophytes is conducted in conditions of «wet mass», it is necessary to take care that no water remains on the thallus. Moisture is removed from the surface of the thallus by drying with a filter paper until the «wet trace» disappears. However, it is necessary not to dry the sample to the state of loss of cellular moisture.

After weighing, the number of thalli are counted for each species which has been identified. These are large perennial forms possessing a distinct rhizoidal part and also sea grasses, with clearly separated plants.

2.4 Measurement of morphological parameters

For the identification of dimensions of population structure, the height of the thalli representing a random sample of the population is measured. Similarly as determining the abundance, the thallus height may be determined only in separated thalli. The sample should consist of not less than 50 thalli. The selected thalli are placed in a dry cuvette or on a filter paper and with the help of a ruler, caliper or roulette tape the distance from the basal to the apical part of the thallus is measured.

For calculating all of the morpho-functional parameters (see 5.2), it is necessary to make statistically significant determinations of parameters which are directly related to the specific surface of the thallus. For macrophytes having a cylindrical form, the parameter is the diameter of the thallus (d), and for macrophytes having a laminated structure – the thickness of the thallus (h). For measuring large cylindrical structures of a few millimeters in diameter, a caliper is used. Measuring of cylindrical structures of a diameter from a few to several hundred mkm is done with a microscope. The preparation is carefully straightened out on the glass slide. The same with measuring of large laminated structures is done with a caliper. In the case of a thin thallus (some tens of mkm), preparations for microscopic observations should be done (see 4.2.).

2.5 Mounting specimens

The final stage for treating the macrophytobenthos is mounting the specimens from whole thalli for a herbarium. A herbarium is not only a convenient form for documenting of material and creating a collection for illustrating the floristic composition in the area under study, but it also has aesthetic, and sometimes even artistic value. The thallus is straightened out with pincers in a wide cuvette

filled with water. A sheet of heavy paper (Whatman) is carefully slipped under so as not to disturb the natural ramification of the sample. The residue water is drained, and it is placed in a «shirt» prepared from a filter paper (a double sheet enclosing the herbarium sheet) and laid under a press. During the first days it is necessary to change the filter «shirt» to drain off the water. This is especially important for species with a «fleshy» thallus, in which there is a danger of mould growth spoiling the herbarium. After completely drying out the herbarium sheet is provided with a detailed label on the place, time and conditions of sampling. A temporary «shirt» from a filter paper can be substituted by a permanent «shirt» from any kind of paper (tracing paper, parchment, polished paper). The herbarium samples in order of system, are placed in a special herbarium cupboard located in well ventilated premises for long storage. Besides this recommendations can be using the "Guidelines by herbarium of marine plants" (Milchakova, 2011).

3 Calculation of indices

3.1 Structural-functional indices

Biomass <in meadow>

The necessity of calculation of this index is that for sampling of macrophytobenthos, the method of visual estimation, allowing to select areas of maximal coverage of the bottom with macrophytes is used. As a rule, periphyton frames are laid in areas with a 100 % projected coverage. Correspondingly, a rise in the value of the algal mass occurs characteristic for the whole area explored. However, such an index, in spite of its high absolute value is useful for describing the potential possibilities of coverage of the bottom vegetation.

For the calculation of the index of biomass «in meadow» (B_{mead}), it is necessary to add the mass of all species fixed in the frame for quantitative account, and then multiply the total mass of the frame by a coefficient showing the size of the frame for calculating on a square meter of the bottom. The V_{mead} index is calculated as:

$$V_{mead} = W\Sigma \cdot C,$$

Where $W\Sigma$ - total mass of fixed species in the sample: C - coefficient of conversion of frame dimensions to m^2 .

Thus the dimensions of macrophyte biomass are expressed in $g \cdot m^{-2}$ or in $kg \cdot m^{-2}$.

For example: In a sample from a periphyton 10 x 10 cm frame, three species of macrophytes were fixed of a mass: $W_1=2.5$ g; $W_2= 4.0$ g; $W_3= 5.3$ g. Herein, the total mass of the sample is: $W\Sigma = 11.8$ g. in a frame equal to 100. Consequently, V_{mead} makes up $1180 \text{ g} \cdot m^{-2}$ or $1.180 \text{ kg} \cdot m^{-2}$.

Average biomass

The index of average microphytobenthos biomass (B_a) shows the real mass of vegetation developing on the explored area taking into account the percentage of projected coverage of the bottom with macrophytes. The value of average biomass V_a can be calculated according to the formula:

$$V_a = V_{mead} \cdot \underline{PC},$$

100%

where V_{mead} is the biomass in meadow; PC is percentage of projected coverage of the bottom of macrophytes.

For example, it was found out that for the explored area the value of the V_{mead} index is 500 (g.m^{-2}). But here the projected coverage of the bottom of macrophytes is equal to 50%. Herein the value of the average biomass will make up 250 g.m^{-2} .

Abundance

As well as in the case of the biomass, the abundance (A) of macrophytes is calculated according to the amount of the thalli fixed in the sample per square meter of the bottom.

$$A = n \cdot C,$$

Where n is the number of thalli in the sample; C – the coefficient of recalculation according to the dimensions of the frame per square meter .

For example, in a $20 \times 20 \text{ cm}$ frame 15 thalli of a certain species of macrophytes were encountered. The abundance of this species is then: $15 \cdot 25 = 375$ thalli per square meter of the bottom.

Shannon Diversity

The condition of the bottom biocenoses is estimated using mainly the Shannon species diversity index to be calculated by means of the formula

$$H_N = -\sum \frac{n_i}{N} \log_2 \frac{n_i}{N}$$

where H_N is the sample's species diversity; n_i is the quantity or biomass of the i-th species (specimens/m^2 or g/m^2), N is the quantity or the biomass of all species (specimens/m^2 or g/m^2).

Production

The production is estimated by means of the Boyznen-Jensen formula (quoted by Babkov, Golikov, 1984) employed when the observation is performed not systematically:

$$P = ((B_2 - B_1) + B_e) / t_2 - t_1,$$

where B_1 is the biomass at the beginning of the period of observation (t_1), B_2 is the biomass at the end of the period of observation (t_2), B_e is the biomass of eliminated individuals calculated as follows:

$$B_e = 1/2 \cdot (B_2/N_2 + B_1/N_1) \cdot (N_2 - N_1),$$

where N_1 and N_2 is the density at the beginning and at the end of the period of observation respectively. In breaks between observations the population should not be augmented by young individuals. It is appropriate to conduct two surveys – at the start and at the end of macrophytic vegetation.

Stock

To obtain the stock of the macrophytes (Q) it is advisable to use the formula proposed by K.P. Gemp (1963):

$$Q = B \cdot TPC \cdot S / 100,$$

where B – average macrophyte biomass (g/m^2), TPC – total projective cover (%), S – square, occupied by macrophytes (m^2). It is also useful to use the correction factor - the cosine of the angle of inclination of the bottom (R), proposed by E.I. Blinova et al. (2005):

$$Q = B \cdot TPC \cdot S / \cos(R) \cdot 100$$

Age and Size-Weight structure

For the Black Sea it is useful to describe the methods for studying the age and size-weight structure of the species which are dominant in the plant communities, namely, *Cystoseira crinita* and *C. barbata*. The investigation is conducted by randomly extracting 30-40 individuals from the sample for which the thallome age, weight and length are determined. The thallome age of *Cystoseira* sp. can be obtained from the formula proposed by A.A. Kalugina-Gutnik (1975):

$$T = B_1 + B_2 / 11,$$

where B_1 is the number of main branches formed in a year, B_2 is the number of "stumps" remaining after the fallen main branches. The age can also be determined from the length of the main stem using for this purpose the equation obtained by V.P. Parchevski and G.V. Parchuk (1979) by means of regressive analysis:

$$T = 0,132 + 0,352 L_m$$

where L_m is the length of the *Cystoseira*'s main stem in cm.

3.2 Morphofunctional indices

From all of the complex of morphofunctional indices which can be calculated for the level of structural elements, thalli, population and community, the most important for monitoring of macrophytobenthos is the specific surface of the population (S/W_p) and the index of the surface of the community (SI_{cm}). However, in the algorithms when calculating these two indices, the stages of calculation of contiguous indices are used for which in this methodical guide the complete algorithms for all six indices are given.

All the morphological variety of the benthos vegetation structure elements, from which the multicellular algal thalli consist and the single plants of the submerged macrophytes, is possible to bring to three main geometric forms: cylinder, lamella and ball. Each of these forms has a parameter, that is directly connected and defines the specific surface value when change the size of the figure. For the ball and cylinder this is the diameter, for lamella - the thickness (Minicheva, 1992).

For the simplification of the specific surface calculation problem it's necessary to take the following relative classification of the morphological types of the benthos vegetation macroscopic forms, on the grounds of which the methods of the specific surface calculation of the structure elements are built (Fig.7).

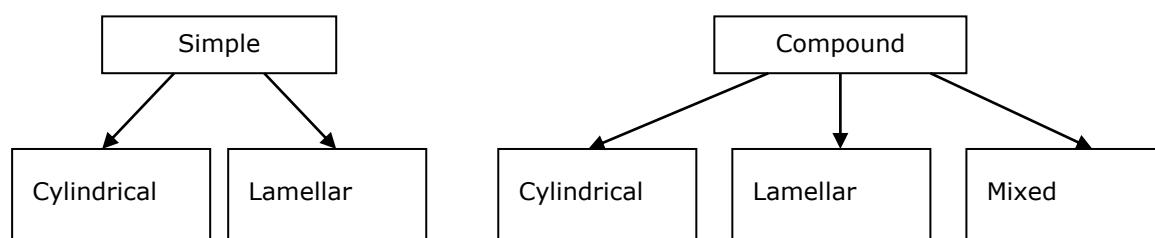

Fig.7. The scheme of the morphological types of the macroscopic forms benthos vegetation.

All the morphological variety of the macrophytes thallus structure given by this scheme is possible to divide into the simple and compound type. The plants pertain to the *simple* type, as its different parts of the thallus have the same morphological form and minor size differences (the maximum value of the functionally depending parameters exceeds the minimum for not more than in 5

times). To the *compound* type of the morpho-functional structure pertain the plants in which composition enter the groups of the structure elements, that have different morphological form, or having essential differences in the parameters functionally connected with the specific surface (the maximum value functionally depending parameters exceeds the minimum for more than in 5 times).

In turn the simple type is divided into the cylindrical and lamellar ones. To the *simple cylindrical* type pertain the plants, which thallus is characterized by cylindrical form and minor diameter size differences values (the maximum value exceeds the minimum for not more than in 5 times). To the *simple lamellar* type pertain the plants of the lamellar form with the close values of the thallus thickness (the maximum value exceeds the minimum for not more than in 5 times).

The compound thallus type is divided into the compound cylindrical, compound lamellar and mixed compound (refer to fig. 7). In the plants of the *compound cylindrical* type exist several structure elements groups for which, the average values of the diameters differ for more than in 5 times. In the plants of the *compound lamellar* type exist several structure elements groups, for which, the average values of the thallus thickness differ for more than in 5 times. To the *mixed compound* type pertain the plants, in which the structure elements groups of the lamellar, cylindrical or spherical forms are present simultaneously.

The specific surface indexes of the multicellular algae and flowering plants

Specific surface of the structure elements (S/W)_{se}

The define methods of the given index (S/W)_{se} has the differences for morphological structures of the cylindrical, lamellar and spherical forms. Earlier, in practice, mostly was used the method of the direct surface area measurement, the main essence of which is brought to the selection of the cognate with the layer form geometric figure and the surface area calculation on the known mathematical formulas. For instance, cylindrical and spherical structures area is possible to calculate on the formulas of the cylinder and the ball. Besides, the S/W layer fragment of the lamellar seaweeds define was done by the "method of the etalon". However a practice has shown that the least labour-intensive and the most suitable method of the specific surface value define is the allometric method (Minicheva, 1992).

The cylindrical type of the structure elements

The value **(S/W)_{se}** of the cylindrical macrophytes is inversely proportional to their diameter.

1. The methods of the specific surface of the structure elements (S/W)_{se} calculation of the simple cylindrical species:

1.1 Prepare the structure elements preparation of the cylindrical type.

1.2 With the help of the microscope (binocular, sliding) to measure the diameter of the structure elements: $d_1, d_2, \dots d_n$.

1.3 To calculate the average reliable value of the structure elements diameters - d_x .

1.4 To conduct the specific surface value calculation on the equation:

$$(S/W)_x = 3334 d_x^{-0,916},$$

where d_x - is an average structure elements diameter (mkm), $(S/W)_x$ - is an average specific surface of the structure elements - **(S/W)_{se}** ($m^2 kg^{-1}$).

The lamellar type of the structure elements

The **(S/W)_{se}** value lamellar macrophytes is inversely proportional to their thickness.

2. The methods of the specific surface calculation of the structure elements $(S/W)_{se}$ of the lamellar type:

2.1 To prepare the preparation of the structure elements transverse cut of the thallus of the lamellar type.

2.2 With the help of the microscope (binocular, sliding) to measure the height of the cut - a structure elements' thickness: $h_1, h_2, \dots h_n$.

2.3 To calculate the reliable average value of the cut thicknesses - h_x .

2.4 To conduct the specific surface value calculation on equation:

$$(S/W)_x = 2000 * h^{-0,988},$$

where h_x - is an average thickness value of the cut (mkm), $(S/W)_x$ - is an average specific surface of the structure elements - $(S/W)_{se}$ ($m^2 kg^{-1}$).

The spherical type of the structure element

The $(S/W)_{se}$ value of the spherical macrophytes is inversely proportional to their diameter.

3. The methods of the specific surface calculation of the structure elements $(S/W)_{se}$ of the spherical species:

3.1 To prepare the structure elements preparation of the spherical type.

3.2 With the help of the microscope (binocular, sliding) to measure the structure elements diameters: $d_1, d_2, \dots d_n$.

3.3 To calculate the reliable average value of the structure elements diameter - d_x .

3.4 To conduct the specific surface value calculation on the equation:

$$(S/W)_x = 6058,87 * d^{-1,0026},$$

where d_x - is an average structure elements diameter (mkm), $(S/W)_x$ - is an average specific surface of the structure elements, equal $(S/W)_{se}$ ($m^2 kg^{-1}$).

Specific surface of the thallus $(S/W)_t$

Simple cylindrical thallus type

The methods of the thallus specific surface calculation of the simple cylindrical type corresponds to the principle algorithm of the to structure element specific surface calculation of the cylindrical type (refer to ii. 1.1 - 1.4).

Simple lamellar thallus type

The methods of the thallus specific surface calculation of the simple lamellar type corresponds to the principle algorithm of the structure element specific surface calculation of the lamellar type (refer to ii. 2.1 - 2.4).

Compound cylindrical thallus type

The compound cylindrical type macrophytes $(S/W)_t$ value is the morphological structures groups sum $(S/W)_{se}$, from which the thallus composes. Herewith the $(S/W)_t$ reflects the composite contribution of all the morphological structure groups , from which the thallus composes.

4. The methods of the thallus specific surface calculation $(S/W)_t$ of the compound cylindrical species:

4.1 To select the structure elements groups in the thallus, ratio between maximum and minimum diameter value that does not exceed 5-times value: $d_1, d_2 \dots d_n$.

4.2 To calculate the specific surface of each structure element group $((S/W)_{se})_1, ((S/W)_{se})_2, \dots ((S/W)_{se})_n$ (refer to ii. 2.1 - 2.4).

4.3 To divide the thallus on the detailed structure element groups and define their weight - $w_1, w_2, \dots w_n$.

4.4 To calculate the value of the external surface of each structure elements group : $s_1, s_2, \dots s_n$ on proportions: $s_i = ((S/W)_{se})_i * w_i$,

where i - is a structure elements group.

4.5 To calculate the total surface and weight of the thallus:

$$\sum_{i=1}^n s_i \text{ и } \sum_{i=1}^n w_i$$

4.6 To correlate the thallus surface s_i to its weight w_i , getting value $(S/W)_t$.

Compound lamellar thallus type

The thallus specific surface of the compound lamellar species $(S/W)_t$ is calculated on the grounds of the $(S/W)_{se}$ values of the lamellar type (refer to i. 2), and corresponds to the principle algorithm of the thallus specific surface calculation of the compound cylindrical type (refer to ii. 4.1 - 4.6).

Mixed thallus type

The specific surface of the thallus of the mixed type $(S/W)_t$ is calculated on the grounds of the corresponding structure elements values $(S/W)_{se}$ (cylindrical (refer to i. 1), lamellar (refer to i. 2) and spherical type (refer to i. 3)), and corresponds to the principle algorithm of the thallus specific surface calculation of the compound cylindrical type (refer to ii. 4.1 - 4.6).

Specific surface of the population $(S/W)_p$

At the specific surface calculation of the macrophytes population is necessary to take into consideration the population structure, which is formed due to the age, dimensional, morphological, and also other heterogeneities, inherent to the populations. In this connection, for the $(S/W)_p$ calculation, it is necessary to have the individual's sample, $(S/W)_t$ which representively reflects the dispersal of the given values within population.

5. The methods of the populations specific surface $(S/W)_p$ calculation:

5.1 On the population growing area, keeping stated step on the locality, is selected a motivated thallus number. At the cylindrical structures diameter before 100 mkm step of the thallus selection forms 15-30 cm. At the greater diameter sizes, the step of the selection is not less than 3-5 m. For the lamellar forms with the layer thickness less than 50 mkm the first variant is available, at the more high values - the second variant is available.

5.2 Using corresponding methods, designed for the thallus specific surface value define of the different morphological type, to calculate the specific surface of the selected thalluses - $(S/W)_t$.

5.3 With the help of the standard methods of the statistical processing, on the base of the got values $(S/W)_{ti}$ to calculate the population specific surface value:

$$(S/W)_p = (\sum_{i=1}^n (S/W)_{ti})/n,$$

where I - a thallus number in the population.

Table 1 presents information about (S/W_p) value for some representatives of macrophyto benthos of northwestern part of Black Sea.

Specific surface of the community (S/W)_c

The (S/W)_c value is an average value (S/W)_{pi}, for all the species of the benthos vegetation, including micro- and macroalgae, and also aquatic plants, incoming in the community.

6. The methods of the community specific surface calculation (S/W)_{cm}:

6.1 To calculate the (S/W)_{pi} values for all the species, incoming to the community (refer to ii. 5.1 - 5.3).

6.2 With the help of the standard methods of the statistical processing, on the base of the got values (S/W)_{pi} to calculate the community specific surface value (S/W)_{cm}:

$$(S/W)_{cm} = \left(\sum_{i=1}^n (S/W)_{pi} \right) / n$$

where i - a population number, incoming to the community.

Benthos vegetation surfaces indexes

Population surface index SI_p

The macrophytes SI_p value characterizes total monocoenosis photosynthesizing surface, formed by species of the bottom vegetation, in calculation on the m^2 of the bottom.

7. Methods of the population surface index SI_p calculation:

7.1 To calculate the specific surface of the investigative population - (S/W)_p. (refer to ii. 5.1 - 5.3).

7.2 Using standard phytocenosis studies methods (Morozova-Vodyanickaya, 1936; Kalugina-Gutnik, 1969; Eremenko, 1980) define the average population biomass - B_p .

7.3 To calculate the population surface index on the formula:

$$SI_p = (S/W)_p * B_p,$$

where (S/W)_p - a specific surface of the population ($m^2 \cdot kg^{-1}$), B_p - a population biomass ($kg \cdot m^{-2}$), SI_p - a population surface index (un.).

Community surface index SI_{cm}

The SI_{cm} value characterizes total photosynthesizing surface of the species, incoming into the community, in calculation on m^2 of the bottom.

8. Methods of the community surface index SI_{cm} calculation:

8.1 To calculate the population specific surface - (S/W)_{pi} of all the species of bottom vegetation, incoming into the structure of investigative community (refer to ii. 5.1 - 5.3).

8.2 Using standard methods of the marine phytocenosis studies (Morozova-Vodyanickaya, 1936; Kalugina-Gutnik, 1969; Eremenko, 1980), define the cenopopulations biomass, composing phytocenosis - B_i .

8.3 To calculate the surface indexes coenopopulations, composing community, on formula:
 $SI_{pi} = (S/W)_{pi} * B_i$,

8.4 To calculate community surface index on formula:

$$SI_{cm} = \sum_{i=1}^n SI_{pi},$$

where i - a coenopopulations number, composing community.

3.3 Ecological Evaluation Indices

It is proposed to consider the possibilities of three macrophytes' morphofunctional indicators, which could be proposed for expressing the Ecological Evaluation (EEI) Index when assessing coastal ecosystems' Ecological Status Class (ESC) based on phytobenthos state (tab. 2).

Table 2. Macrophytes' morphofunctional indicators proposed for assessment of marine coastal ecosystems' ESC

Indices	Calculation formula
Three Dominants Ecological Activity, S/W_{3DP}	$S/W_{3DP} = \frac{\sum 3(S/W)_{pi}}{3n}$ <p style="text-align: center;">where: S/W_{pi} - specific surface of populations of three first phytobenthos dominants</p>
Average Species Ecological Activity, S/W_x	$S/W_x = \frac{\sum (S/W)_{pi}}{ni}$ <p style="text-align: center;">where: S/W_{pi} - specific surface of all populations in the community</p>
Phytocenosis Surface Index, SI_{ph}	$SI_{ph} = \sum (B_{pi} \times (S/W)_{pi})$ <p style="text-align: center;">where: S/W_{pi} - specific surface of phytocenosis populations; B_{pi} – biomass of phytocenosis populations</p>

As all the proposed morphofunctional indicators have their advantages and disadvantages (tab. 3) expert decision on each specific morphofunctional indicator choice as the EEI should be taken depending on specific task of a study.

Table 3. Comparison of advantages and disadvantages of macrophytes' morphofunctional indicators proposed for coastal ecosystems' ESC assessment

Indicator	Advantages	Disadvantages
Three Dominants Ecological Activity, S/W_{3DP}	<ul style="list-style-type: none"> - Efficient for comparative express-assessment of ecosystems with different floristic composition. - Low level of labour input. - Low probability of computation error. - Low level of user's qualification. 	<ul style="list-style-type: none"> - Characteristics of artificial phytosystem (only first three dominants). - Low sensitivity for short-period (seasonal) monitoring of ESC for water bodies with perennial dominants.
Average Species Ecological Activity, S/W_x	<ul style="list-style-type: none"> - High sensitivity for temporal (seasonal, long-period) monitoring of ESC in water bodies with simplified species composition. 	<ul style="list-style-type: none"> - High level of labour input. - High probability of computation error. - High level of user's qualification.
Phytocensis Surface Index, SI_{ph}	<ul style="list-style-type: none"> - Characteristics of natural phytosystem (phytocenosis – basic unit of vegetation). - High sensitivity for spatial and temporal monitoring. 	<ul style="list-style-type: none"> - High level of labour input. - High probability of computation error - (loss of biomass on upper

	- Possibility of historical databases recalculation on structural parameters.	horizons).
--	---	------------

The proposed EEI classification schemes could be used to assess the ESC of water bodies in Ukrainian sector of the Black Sea ecosystem, as for determination of their parameters we have used the data on macrophytes' morphofunctional organization from the Danube Delta to the Strait of Kerch, including limans ecosystems (tab.4). Given that the EEI classification schemes covers the almost possibility range of morphofunctional organization of Black Sea's macrophytobentos (in spite of the data were obtained only with Ukrainian sector) at this stage it can be used to regional monitoring. However, in future these classification schemes would require intercalibration taking into account the values of macrophytes' morphofunctional indicators for other National coasts of the Black Sea.

Table 4 EEI classification scheme for macrophytes' morphofunctional indices

ESC	EEI range					
	$(S/W)_{3Dp}$, $m^2 \cdot kg^{-1}$	EQR	$(S/W)_x, m^2 \cdot kg^{-1}$	EQR	SI_{ph} , units	EQR
High	$(S/W)_{3Dp} < 15$	≥ 0.82	$(S/W)_x < 60$	≥ 0.98	$SI_{ph} < 25$	≥ 0.95
Good	$15 \leq (S/W)_{3Dp} \leq 30$	0.54	$60 \leq (S/W)_x \leq 80$	0.79	$25 \leq SI_{ph} \leq 40$	0.84
Moderate	$31 \leq (S/W)_{3Dp} \leq 45$	0.37	$81 \leq (S/W)_x \leq 120$	0.58	$41 \leq SI_{ph} \leq 65$	0.55
Poor	$46 \leq (S/W)_{3Dp} \leq 60$	0.25	$121 \leq (S/W)_x \leq 200$	0.17	$66 \leq SI_{ph} \leq 90$	0.15
Bad	$(S/W)_{3Dp} > 60$	≥ 0	$(S/W)_x > 200$	≥ 0	$SI_{ph} > 90$	≥ 0

General notes

For successful monitoring of the states of coastal ecosystems while using macrophytobenthos, an important condition is the selection of a location and time performance for conducting the survey. Alternative stations for monitoring macrophytobenthos, are located in clean open sites, coastal areas with good water exchange, natural substrate, as well as in sites with the greatest man-made load and artificially changed biotopes. The optimum length of time between macrophytobenthos sampling should be 1 month. Minimum frequency of performance of sampling - once per season.

Agreement of works performed on location and time of monitoring surveys of macrophytobenthos between representatives of all Black Sea countries, will enhance the effect of the assessment of a contemporary state and the making of decisions for optimum management of regional coastal ecosystems. Another problem that has now become relevant for monitoring of the Black Sea to harmonize of macrophytobentos indicators to EC Directives: WFD and MSFD.

Software:

- [spreadsheet application](#), for simple statistical calculation and common graphing: **Microsoft Excel (Excel 2007, Excel 2010, Excel 2013, Excel 2014)** (commercial software)
- data analysis, data management, data visualization, and data mining procedures: **Statistica (Statistica 6.0, Statistica 7.0, Statistica 7.1, Statistica 8.0, Statistica 9.0, Statistica 9.1, Statistica 10.0, Statistica 11.0, Statistica 12.0)** (commercial software)
- advanced statistical computing and graphics: **R-PROJECT (R version 3.0.3, R version 3.1.1)** (freeware)
- advanced statistical computing and graphics of ecological data (grouping, sorting, principal component identification, hypothesis testing, sample discrimination, trend correlation, comparisons, diversity, dominance and distribution calculating, permutational multivariate analysis of variance): **PRIMER (PRIMER 5. PRIMER 6)** (commercial software)
- advanced multivariate statistical analysis using ordination methods in the field of ecology and several related fields: **Canoco (Canoco 4.0, Canoco 4.5, Canoco 5)** (commercial software)
- multivariate analysis of ecological data entered in spreadsheets: **PC-ORD (Version 6)** (commercial software), **MULVA** (freeware)
- **- for visualizing phylogenetic trees and rooted networks:** Dendroscope (Dendroscope 3) (**freeware**)
- a database management system for the storage, selection and export of vegetation data: **Turboveg (Turboveg 2, Turboveg 2.5, Turboveg 3)**
- software package for editing and analyses of phytosociological data: **JUICE (JUICE 7.0)** (freeware)
- for table classification and sorting: **TWINSPAN** (freeware)
- for mapping of species, species group or relevé distribution: **DMAP** (commercial software)

Annex 3 Macrophytobenthos Indicators for Black Sea Monitoring*

Proposed criteria for selection:

- Reflection of the structure functional organization or autotrophic process
- Easy to calculate based on the collected/monitoring available data
- Define quality classes/boundaries
- Sensitiveness to the anthropogenic load
- Correspond to MSFD requirement
- BS policy relevance

No	Indicators name	Index, Unit
Qualitative (State Indicators)		
1.	Community diversity	Number of species, Number of taxonomic group
2.	Status of key species	Systematic, saprobe status, Red Data Book status, long live cycle (perennial, ephemeral)
3.	Threatened species	Number, status
4.	Disappear species	Number, status
5.	Invasive species	Abundance, Cover, Biomasses, Distribution map
6.	Recovered species	Cover, Biomass, Distribution map
7.	Returning species	Cover, Biomass, Distribution map
Quantitative (Response Indicators)		
8.	Changes of lower depth distribution limit of macrophytes	m (for last specimen with min. 10% coverage)
9.	Changes of coverage bottom by macrophytes	Percent coverage of bottom
10.	Biomass of community (on meadow, average)	kg.m ⁻²
11.	Trends of Phytocoenoses Surface Index (SI _{ph})	units
12.	Biomass and abundance of dominant species	kg.m ⁻²
13.	Age and size structure of dominant species	Distribution diagrams of classes
14.	Trend of ecological activity (S/W _p) of replaces dominants	m ² .kg ⁻¹
15.	Biomass and abundance of key species	kg.m ⁻² , n.m ⁻²
16.	Production and stock of commercial macro algae and sea grasses	kg.m ⁻² .year ⁻¹ , tone per investigate area
17.	Ratio of opportunistic and perennial macroalgae (biomass)	%
18.	Ratio of above-and belowground biomass of seagrasses	%

No	Indicators name	Index, Unit
<i>Ecological Evaluation Index</i>		
19.	Three dominants activity (S/W _{3Dp})	m ² .kg ⁻¹ , classification scheme for 5 Ecological Status Classes correspond to MSFD
20.	Community activity (S/W _{xcom})	m ² .kg ⁻¹ , classification scheme for 5 Ecological Status Classes correspond to MSFD
21.	Phytocoenoses Surface Index (SI _{ph})	Units, classification scheme for 5 Ecological Status Classes correspond to MSFD
22.	Ecological Status Groups (ESG) ESG I, (k-selected species), (IC, IB, IA); ESG II, (r-selected species), (IIB, IIA).	% - ratio between species of ESGI and ESGII, classification scheme for 5 Ecological Status Classes correspond to MSFD

* Macrophytobenthos indicators were discussed by the authors with Dr. Natalya Milchakova (Institute Biology of Southern Seas the name of A.O. Kovalevskiy, Sebastopol) at a meeting of EMBLAS project, 14-17 July 2014 in Istanbul.
